C1 Contents of this document

This documents presents the results of Matlab simulations, presenting theoretical implications of the game rules and the consequences of empirical choices made by participants. The document is structured as follows:

- Description of the general procedure used for simulations, and the definition of decision strategies and conditions (section SIM-2)
- Explanation of figure types used to visualize results (section SIM-3)
- Simulations based on the empirical data for each of the eight experimental conditions (section SIM-4)
- Simulations based on the empirical data for framing and intervention combinations joining the two partisan samples (section SIM-5)
- Comparison of results between conditions (section SIM-6)
- A full collection of the simulation code used to generate the presented results (section SIM-7)

C2 Simulation procedure

C2.1 Number of trials

If not otherwise specified, reported data are based on 1,000,000 trials per condition or level of the parameter at interest. The simulation code document lists all codes used to generate the data that is used as input for the calculations below.

C2.2 Decision strategies

As in our previous publication Woike et al., 2022, we classify participant behavior during the game into four exclusive qualitative behavioral strategies. The Matlab code

classifies each set of a player's actions into one of these four types:

1. **AllG**: AllG-patterns consist of G-choices from the first to the last round.
2. **HthenG**: H(then)G patterns start with H and from some round on switch to G for the rest of the game.
3. **Switch**: Switch-patterns also alternate between H and G. They either start with G, switch between actions more than once, or have both features.
4. **AllH** : AllH-patterns consist of H-choices from the first to the last round.

Note that the AllG-player chooses the safer option throughout the game, and the AllH-player chooses the riskier option throughout the game. As discussed in the Supplementary Material for the Transmission Game, a pattern of choosing H-actions before switching to G for the rest of the game leads to better expected outcomes than a pattern of switching repeatedly between G and H (or starting with G and switching to H).

For each of these patterns and each game the Matlab code records:

- the number of players with the pattern (can be 0)
- the proportion of blue ("healthy") players among those that play the pattern at the end of the game
- the average outcome for players with this pattern (a purple player scores 0)

This results in 12 collected values per game, with information available in the output files on mean, standard deviation, and percentiles.

C2.3 Simulation conditions

We simulate games for a total of 12 conditions, split into two different sets. The first set of eight conditions is based on mutually exclusive samples of participants. The eight groups are formed by the combination of three binary factors: voter group (2016 presidential election), intervention type and framing.

- **Condition 1**: Trump voters — injunctive norms intervention — Mask framing ($n_1 = 101$)
- **Condition 2**: Trump voters — injunctive norms intervention — Color framing ($n_2 = 99$)
- **Condition 3**: Trump voters — no intervention — Mask framing ($n_3 = 105$)
- **Condition 4**: Trump voters — no intervention — Color framing ($n_4 = 93$)
- **Condition 5**: Clinton voters — injunctive norms intervention — Mask framing ($n_5 = 103$)
- **Condition 6**: Clinton voters — injunctive norms intervention — Color framing ($n_6 = 108$)

- **Condition 7:** Clinton voters — no intervention — Mask framing ($n_7 = 103$)
- **Condition 8:** Clinton voters — no intervention — Color framing ($n_8 = 107$)

The second set of conditions only uses two factors to create four non-overlapping groups of participants: intervention type and framing. Trump voters and Clinton voters are part of the same simulation in each condition.

- **Condition 9:** injunctive norms intervention — Mask framing ($n_9 = 204$)
- **Condition 10:** injunctive norms intervention — Color framing ($n_{10} = 207$)
- **Condition 11:** no intervention — Mask framing ($n_{11} = 208$)
- **Condition 12:** no intervention — Color framing ($n_{12} = 200$)

In practice, this means that, for example, Condition 1 and Condition 5 are collapsed into Condition 9.

C2.4 Sample selection

The differences in sample size required a procedure to select a player group of $n = 100$ in each simulation run. This was achieved by taking a random subsample of the eligible participants in each condition. For conditions, in which the number of eligible participants was below 100 (conditions 2 and 4) this was done with replacement (participants' choice vectors could be selected more than once into the population), for all other conditions this was done without replacement.

C2.5 Data preparation

This document was prepared in Overleaf, as an Rtex file implementing knitr. Any output is generated by R during compilation, and can thus be replicated by entering the same commands referencing the same dataset. Simulation results obtained in Matlab were produced prior to the compilation of this document. Overleaf's R version and selection and versions of packages are not under the user's control. This section demonstrates the R version and the list of packages used for calculations and output generation.

C2.5.2 ggfan

The library `ggfan` was inserted manually in this document by copying the code from <https://github.com/jasonhilton/ggfan/tree/master/R> for "ggfan" and "stat_interval" on 01.09.2023 in version v0.1.3. The code is not echoed into this document but it is executed at this point.

C2.5.3 ggthemes

Parts of the library `ggthemes` were inserted manually in this document by copying the code from <https://github.com/jrnold/ggthemes> for "economist" and "theme_foundation" on 06.09.2023 in version v4.2.4. Calls to load The code is not echoed into this document but it is executed at this point.

```
## NULL
## [1] ".data"
```

C3 Plot types in this document

C3.1 Percentile plots of "infection" rates

The plot calculated below summarizes the data from simulated games using artificial data. In a first example, we simulated 1,000,000 games with a population of 50 All-H players and 50 All-G players. These results were obtained when preparing the supplementary materials for our previous study.

The Matlab code outputs files with percentile summaries of roundwise rates of purple or infected players (henceforth interchangeably also called "infection rates" in analogy to the spread of a virus). Each row corresponds to a value marking the output of the "prctile"-function with the parameter varying from 0 to 1 in 200 increments of 0.5% (including 0 and 1, thus 201 rows). Each column corresponds to the state after each round, with the first column describing the initial state (named "After round 0" to stay consistent). The data is given in wide format. It is reshaped into long format below. The percentile parameters are added to the data set and used as quantile values to the `ggfan`-command. Columns names are manually assigned, but ultimately transformed into numbers.

```
dataRaw=read.delim(
  file="res/PropStable-10----HalfPercentileInfectionRate.txt",
  header=FALSE,col.names=c("R00", "R01", "R02", "R03", "R04",

the
## '.groups' argument.
```

**Figure C1**

Percentile plot for games with 50% AllG-players and 50% AllH-players. Shaded areas mark intervals (prediction intervals, PI) that contain the specified inner percentage of results (number of purple players in the beginning and after each of the 25 rounds). For example, the 95% encompasses the area between the percentile values for 2.5% and 97.5%. On each side, 2.5% of the observed simulation results were more extreme. The dashed lines mark the maximum and minimum value observed across 1,000,000 simulation runs.

Figure C1 shows the variability and central tendency (median) of simulation outcomes. Median, maximum, and minimum are shown as lines (connecting the 26 valid values; the lines between rounds are connected for illustration purposes, even if they are technically meaningless).

Areas correspond to certain percentages of simulated results in the middle of the observed distribution. Specifically, "10%" corresponds to the inner 10% of values, between 45% and 55% of the ordered distribution. In the same vein, 25% corresponds to the inner 25% of the distribution, other values shown are 67% and 95%. This means, that 2.5% of the total distribution lie between the outline of the colored area and the extreme values (on either side).

Not surprisingly, due to path dependency the spread increases over time. Given an infinite number of trials, the minima would be expected to form a straight line, the maxima a rectangular shape. Given the large number of trials, the median line would not change substantially in all likelihood.

These PI-intervals should not be confused with confidence intervals. The 95%-CI for the mean proportion (not shown in the figure) corresponds to an absolute deviation smaller than 0.1% for 1,000,000 trials (with a maximum for an observed proportion of 0.5). The PI intervals estimate the distribution of single results, not mean results.

The median is not always in the middle of the 10% interval, but it obviously could never escape it. This is due to the fact that each trial generates outcomes in 1% increments. Typical values are very compressed at the beginning of the game, so there are relatively many identical outcomes after the first rounds. All games are initialized with 8 purple players, thus all lines start at point (0,0.08). The figure shows the expected rate of infected players (as proportion) throughout the simulated games. The majority of players is infected by round 20 and most games reach infection rates between 60% and 70% at the end of the game. Most players would not receive any bonus money.

C3.2 Results for player types

Two more diagram types illustrate strategy-specific outcomes. We describe outcomes on two main dimensions: The first dimension is the probability of survival, that is, the chance to end the game in a blue or healthy state. Only surviving players earn bonus money. The second dimension is the expected number of points that are translated into payoffs. This dimension is not independent of survival, as non-surviving players score zero points.

C3.2.1 Survival rate

Figure C2 presents results for the simulated data with 50% AllG and 50% AllH players. In this simulation, only two strategy types occur. The figure demonstrates the distribution of survival rates split by strategy type, showing mean, minimum and maximum survival rates across 1,000,000 games and three percentile ranges bracketing the inner 25%, 67% and 95% of results. It is evident that AllG-players have a higher "survival rate" (proportion of staying blue till the end of the game) than All-H players, reflecting the smaller risk taken in each interaction.

**Figure C2**

Distribution of the proportion of blue players at the end of the game (“survival rate” for both player types and the whole population).

C3.2.2 *Expected outcome*

Figure C3 offers an analogous presentation for average point outcomes. Note that non-surviving players lose all of their points. Their scores are thus counted as zero. The two specific strategy types accumulate 200 and 1,000 points, respectively. The average outcome in each game is equivalent to the product of these numbers with strategy-specific survival rates. Even when considering this difference in survival rates, AllH-players have still a higher expected outcome compared to AllG-players.

```

```

Figure C3

Distribution of final scores for both player types and the whole population: These numbers reflect that purple players score zero points at the end of the game. Using the incentive structures in the studies, the average result translates into average payments in pence by dividing final scores by 2.

In monetary terms, AllG players stand to win £1.00, because they invariably score 200 points. AllH players, in contrast, stand to win £5.00, and their survival rate is more than a fifth of the rate for AllG-players. The individual gain in expected outcomes comes at the cost of a reduction of both individual and population survival chance. The supplementary materials accompanying our previous article demonstrates this in a series of simulations.

C4.3 Condition 3: Trump voters/No intervention/Mask framing

C4.3.1 Calculations

**Figure C5**

A) Percentile plot of roundwise purple/infection rates across 1,000,000 simulations for condition 2. B) Distribution of the proportion of blue/healthy players at the end of the game for all player types and the whole population. C) Distribution of final scores for all player types and the whole population.

Figure C8

A) Percentile plot of roundwise purple/infection rates across 1,000,000 simulations for condition 5. B) Distribution of the proportion of blue/healthy players at the end of the game for all player types and the whole population. C) Distribution of final scores for all player types and the whole population.

C4.7 Condition 7: Clinton voters/No intervention/Mask framing

Please note that few players chose to play the All-H strategy in this condition. Some of the represented quantiles therefore coincide in this condition.

C4.7.1 Calculations

**Figure C9**

A) Percentile plot of roundwise purple/infection rates across 1,000,000 simulations for condition 6. B) Distribution of the proportion of blue/healthy players at the end of the game for all player types and the whole population. C) Distribution of final scores for all player types and the whole population.

Figure C15

A) Percentile plot of roundwise purple/infection rates across 1,000,000 simulations for condition 12. B) Distribution of the proportion of blue/healthy players at the end of the game for all player types and the whole population. C) Distribution of final scores for all player types and the whole population.

```

Figure C23

Comparison of expected outcomes across four experimental conditions split by strategy for bipartisan groups: Each bar represents the average expected outcome after the game across 1,000,000 simulations (with purple/infected participants scored as 0). Bars correspond to the expected outcome for those playing a specific strategy in a specific combination of frame and intervention condition (with groups sampled randomly from both Clinto and Trump voters in each simulation). Blue bars correspond to the color frame, black bars to a mask frame. The two leftmost bars in each group correspond to conditions without intervention, the two rightmost bars to condition with intervention. Each group is marked by the respective combination of frame and strategy. 'Pop' refers to results for the entire population in the given frame.

C7 Simulation Code

The following Matlab listing contain the simulation code used for producing the input for the preceding figures. The original code underwent minor modifications here. The following changes were made for readability:

- A Matlab prettifier was used for formatting of the code.
- Function names had some version information in the function name in the original code that was eliminated in this representation.
- A legacy element that was rendered redundant through parameter settings was taken out of the original code. In a variant of the game preceding the original study, a constant round risk was implemented for every population member. This was set to 0 in the original code and therefore had no impact on the results.
- A local foldername was replaced by a variable that stays undefined in the top level routine.
- The routine for loading in the empirical data contained several thousand lines of numbers that were abbreviated in the reproduction below.

C7.1 Top level routine

Noe that the variable saveFolderRoot is not defined in this code, it refers to a local file folder.

Listing 1: Top level routine

C7.2.2 Loading the empirical data

NOTE: XXX dataFile codes voter This routine is reproduced in shortened form: For each round, data for each participant was entered in separate lines. The variable "condition" codes framing and intervention conditions, the variable "datafile" the group of voters (the survey data was stored in two different source files, originally). The code below skips thousands of lines containing roundwise information for choices.
